# MOBILITY PATTERNS AND URBAN STRUCTURE

# Transport and Mobility Series

Series Editors: Richard Knowles, University of Salford, UK and Markus Hesse, Université du Luxembourg and on behalf of the Royal Geographical Society (with the Institute of British Geographers) Transport Geography Research Group (TGRG).

The inception of this series marks a major resurgence of geographical research into transport and mobility. Reflecting the dynamic relationships between socio-spatial behaviour and change, it acts as a forum for cutting-edge research into transport and mobility, and for innovative and decisive debates on the formulation and repercussions of transport policy making.

*Also in the series*

Sustainable Railway Futures  
Issues and Challenges

*Edited by Becky P.Y. Loo and Claude Comtois*  
ISBN 978 1 4094 5243 0

Institutional Challenges to Intermodal Transport and Logistics  
Governance in Port Regionalisation and Hinterland Integration

*Jason Monios*  
ISBN 978 1 4724 2321 4

Port-City Interplays in China

*James Jixian Wang*

# List of Figures

1.1	Research methodology: combined application of SAL and EQQM	4
2.1	Types of urban systems	16
2.2	Types of urban structures in Europe	17
2.3	Classification of urban structures	18
3.1	Summary of the main household characteristics influencing travel patterns	24
3.2	Summary of the urban structure characteristics influencing travel patterns	30
3.3	Main household and urban structure factors influencing travel behaviour	35
4.1	Europe, Denmark and the Copenhagen Metropolitan Area	38
4.2	Changes in the population size of Greater Copenhagen since 1971	39
4.3	Changes in the population size within different parts of Greater Copenhagen since 1971	40
4.4	Distribution of the population of Greater Copenhagen between age groups	40
4.5	Changes in the regional GDP of the Capital Region of Denmark since 1993. Current values have been adjusted to fixed 2005 values	42
4.6	Changes in the regional GDP per capita of the Capital Region of Denmark since 1993. Current values have been adjusted to fixed 2005 values	42
4.7	Gross value added by different trades within the combined statistical units ('landsdele') of 'the city of Copenhagen' and 'the surroundings of Copenhagen'	43
4.8	Unemployment rates within different geographical parts of Denmark	43
4.9	Changes in purchasing power per capita since 2000 within the combined statistical units ('landsdele') of 'the city of Copenhagen' and 'the surroundings of Copenhagen'	44
4.10	Changes in purchasing power per capita since 2000 within different parts of Greater Copenhagen	45
4.11	Population density in Copenhagen Metropolitan Area	46
4.12	Employment density in Copenhagen Metropolitan Area	47

4.13	Neighbourhood densities (inhabitants and jobs per area unit) in investigated residential areas in different distances from the city centre of Copenhagen	48
4.14	Percentages of different land use categories in Greater Copenhagen	49
4.15	Greater Copenhagen land use in 2000	50
4.16	Road and rail infrastructure and public transport lines in Copenhagen Metropolitan Area and in Greater Copenhagen	52
4.17	Modal share in Greater Copenhagen	53
4.18	Purpose of trips in Greater Copenhagen	53
4.19	Changes in population density within the continuous urban area of Greater Copenhagen	54
4.20	Europe, Portugal, Greater Oporto and its municipalities	60
4.21	Evolution of the number of inhabitants in Greater Oporto	60
4.22	Evolution of the number of inhabitants in each Greater Oporto municipality	61
4.23	Distribution of the population of Greater Oporto between age groups	61
4.24	Evolution of the GDP (millions of euro) in Greater Oporto	62
4.25	Yearly variation of the GDP	63
4.26	Evolution of GDP per capita (1000s of euro) between 1995 and 2008 in Portugal, North Region and Greater Oporto	63
4.27	Yearly variation of the GDP per capita in Portugal, North Region and Greater Oporto	64
4.28	Unemployment rate in Portugal, North Region and Greater Oporto	64
4.29	Unemployment rate in Greater Oporto municipalities	65
4.30	Gross value added (millions of euro) in Greater Oporto	65
4.31	Purchasing power in Greater Oporto	66
4.32	Evolution of purchasing power in Greater Oporto municipalities	67
4.33	Areas of land use categories in Greater Oporto	68
4.34	Greater Oporto land use in 2006	69
4.35	Population density in the Oporto Metropolitan Area	70
4.36	Employment density in the Oporto Metropolitan Area	71
4.37	Neighbourhood densities (inhabitants and jobs per area unit) in investigated residential areas in different distances from the city centre of Oporto	72
4.38	Road and rail infrastructures and public transport lines in Greater Oporto	73
4.39	Modal split in Greater Oporto	75
4.40	Trip purpose in Greater Oporto	75
4.41	The overlay of the two study areas	78
5.1	Accessibility boundaries by transport mode drawn for two theoretical origin points	83
5.2	Potential combinations of accessibility values by three transport modes	84

5.3	Benchmarking cube and accessibility classes by transport mode	85
5.4	Benchmarking cube and accessibility clusters	86
5.5	Case-specific choices	88
5.6	Potentials and limitations of the SAL	93
5.7	Case-specific benchmarking cube	99
6.1	Location of the investigated residential areas (and population density) in Greater Copenhagen	110
6.2	Location of the investigated residential areas (and population density) in Greater Oporto	111
7.1	Diversity of activity index by walking in GC	122
7.2	Diversity of activities accessible by bicycle in GC	124
7.3	Diversity of activities accessible by public transport in GC	126
7.4	Diversity of activities accessible by car in GC	128
7.5	Clusters of accessibility in GC	129
7.6	Clusters of accessibility in GC (with bicycle)	131
7.7	Diversity of activities accessible by non-motorized modes in GO	133
7.8	Diversity of activities accessible by public transport in GO	135
7.9	Diversity of activities accessible by car in GO	137
7.10	Clusters of accessibility in GO	138
7.11	Diversity of activity index in the two regions of study	142
7.12	Population density in the two regions of study	143
7.13	Clusters of accessibility in GC and GO	146
8.1	Mean weekly total travel distances among respondents living in residential areas in Greater Copenhagen (black dots) and Greater Oporto (white circles), located at different distances from the city centres (left), and with different neighbourhood densities (right)	162
8.2	Mean weekly total travel distances among respondents living in residential areas in Greater Copenhagen (black dots) and Greater Oporto (white circles), located at different distances from the closest second-order centre (left), and from the closest urban rail station (Copenhagen) or main regional retail centre (Oporto) (right)	163
8.3	Predicted average weekly total travel distances among respondents living in residential areas in Greater Copenhagen (black dots) and Greater Oporto (white circles), located at different distances from the city centres (to the left), and with different neighbourhood densities (to the right)	167
8.4	Predicted average weekly travel distances by non-motorized modes among respondents living in residential areas in Greater Copenhagen (black dots) and Greater Oporto (white circles),	

located at different distances from the city centres (left), and with different neighbourhood densities (right) 175

# Notes on Contributors

**Fabrizio Giulietti** has a PhD in Spatial Planning Evaluation and Environmental Policy Analysis, an MSc in Mobility Planning and Management, and a BA in Sociology of Economy. He is an M&E consultant in sustainable integrated (physical and socioeconomic) development of the urban environment, transport and accessibility planning, and climate protection initiatives. His fields of expertise interests include cities competitiveness and innovation, as well as land use and infrastructures regional planning.

**Petter Næss** is Full Professor in Planning in Urban Regions at the Norwegian University of Life Sciences, and member of the Executive Board of the World Society for Transport and Land Use Research (WSTLUR). Combining qualitative and quantitative research methods, for more than two decades he has carried out research into the influences of urban structures on travel behaviour.

**Paulo Pinho** LEng, Dipl U&RP, PhD, is Full Professor of Spatial and Environmental Planning at the Faculty of Engineering, University of Oporto (FEUP), founder and Director of CITTA, the Research Centre for Territory, Transports and Environment, and Secretary General of AESOP (2015–2019), the Association of European Schools of Planning. His recent research focuses on urban and metropolitan morphology, dynamics and transport systems, and on urban metabolism and low carbon cities.

**José Pedro Reis** is a PhD candidate at the Department of Land Economy, University of Cambridge. He has a Master's in Civil Engineering with specialization in Urban Planning from the Faculty of Engineering of the University of Porto. His main research interests are the study of urban form, the processes of urban growth and shrinkage, and urban planning policy.

**Cecilia Silva** is Assistant Professor at the Faculty of Engineering, University of Porto (FEUP). Her main research fields are on mobility management, accessibility planning and planning support instruments. She chaired the COST Action on Accessibility Instruments for European Planning Practice involving 22 countries and more than 100 members (2010–2014).

**Fernanda Sousa** is Assistant Professor of Mathematics at the Faculty of Engineering, University of Porto (FEUP), member of CITTA (the Research Centre for Territory, Transports and Environment), President of CLAD (Portuguese Association of

Classification and Data Analysis) and member of the IFCS Council Committee (International Federation of Classification Societies).

**Miguel Torres** is a Geospatial Developer at UNEP-WCMC. He holds Master's in Civil Engineering from the Faculty of Engineering, University of Porto (FEUP), with specialization in urban planning. He worked on several research projects on land use and transport planning and supervised a local master plan in an African city.

# Acknowledgements

Most of the research portrayed in this book was carried out at the CITTA Research Centre for Territory, Transports and Environment and funded by the FCT – Fundação para a Ciência e a Tecnologia (the Portuguese Foundation for Science and Technology) – through the research contract no. PTDC/ECM/81123/2006.

The authors are thankful to the FCT for the necessary funding, and to their CITTA colleagues for providing a friendly and stimulating working environment throughout the three-year period of the project, which made research a most pleasant and rewarding intellectual activity.

In particular, the editors would like to thank the dedication and excellent collaboration provided by the researchers and book contributors, José Pedro Reis, Miguel Torres, Fabrizio Giulietti, Fernanda Sousa and, with a most deserved reference, Petter Næss, for sharing with the rest of the ‘southern based’ research team his ‘Nordic’ experience that made all the comparative exercise of research methodologies and case studies applications most useful and enlightening. We would also like to thank all undergraduate and postgraduate students who participated in the extensive data collection and compilation, in particular Luisa Batista for collecting and exploring the qualitative insights on travel behaviour (through a number of interviews).

Finally, the authors would also like to express a word of thanks to the anonymous referees and to the series editors for the constructive and valuable criticisms on earlier versions of this book.

# Chapter 1

## Introduction

Paulo Pinho and Cecília Silva

### **Context**

Over the last few years there has been a growing consensus in the scientific literature on the need for innovative policy measures to reduce the environmental impact and the greenhouse gas emissions of urban mobility patterns. To make these actions efficient, policy measures must act on the factors influencing travel patterns and not simply on their symptoms. Therefore, a thorough understanding of the reasons underlying trip making is most required.

In both developed and emerging countries, travel has been rising, presenting more complex patterns and becoming more difficult to predict. The research areas concerned with the study of the factors and motivations underlying travel behaviour have also become increasingly complex, taking into consideration an ever-growing number of investigated aspects and disciplinary perspectives. The research field is vast but somehow disarticulated, lacking a systematic methodological approach, as well as, in most cases, a genuine concern on its applicability to policy making. Land use, transports and individual characteristics are generally considered part of the most important factors influencing travel behaviour.

Most publications reflecting on the factors influencing travel behaviour are individual case studies evaluating the influence of land use. Many of these case studies have arrived at different results and conclusions (for broad literature reviews on this topic see, for instance, Handy, 1996; Ewing and Cervero, 2010; van Wee, 2002). The volume of literature on how land-use patterns and the built environment influence urban travel demand has virtually exploded over the past decade. It is fair to say that most authors believe that land use does have an influence on travel behaviour (e.g., Handy, 1996; Cervero and Kochelman, 1997; Ewing and Cervero, 2010; van Wee, 2002) although, so far, many are sceptical about the composition and decisive nature of the influencing factors, because research methodologies do not seem solid enough, and the case study comparison of results is often difficult if not misleading. Indeed, many case studies have not produced conclusive findings reinforcing the scepticism on the real influence of land use on travel choice. Besides case studies and literature reviews, considerably less research is found on land use policy implications and recommendations. Furthermore, in spite of the extensive research carried out so far on the land use factors influencing travel behaviour, no general consensus has been reached.

This is also the case for research on the influence of transports or of individual characteristics on travel behaviour.

In the bibliography relating travel behaviour to individual characteristics a wide range of study themes can be found. The research in this field can be broadly categorized as focussing on demographic and socioeconomic characteristics of the populations in addition to motivational factors of a psychological nature. Examples of motivational factors, which can be found in this field of research, are, for instance, preferences (Scheiner and Kasper, 2002), value orientation (Scheiner and Kasper, 2002), needs, desires and symbolic affective motives (Steg et al., 2001), habits (Fujii and Kitamura, 2003), and beliefs and attitudes (Fujii and Kitamura, 2003). Case studies evaluating the influence of transport factors on travel behaviour are difficult to find. Research in this field seems to consider this influence as a matter of fact since it tends to concentrate on the formulation of policy measures. Within this research field, most studies evaluate attitudes towards and/or the effect of Transport Demand Management measures (or simply presented TDM measures), and their categorization (see, for example, Marshal and Banister, 1997; and Viegas, 2001). Although the influence of transport systems on travel behaviour is clear and therefore might be exempted from further considerations, the lack of research on the main factors responsible for that influence is one of the main flaws within this research area, especially bearing in mind the corresponding void in policy making this lack of understanding represents.

In spite of the amount of research centred on the factors influencing travel behaviour no consensus can be found in the literature on common orientations for further research. In this context, we intend to build a broader consensus on the factors influencing travel behaviour, being concerned, in particular, with both the influence of urban structure factors (namely, land use and transport system factors) and of motivational factors related to the social, economic and cultural characteristics of the individual traveller.

In recent years, in both developed and emerging countries, mobility patterns have undergone significant changes. The escalating use of the private car for the satisfaction of ever-growing travel needs has contributed, among other factors, to undermine the quality of life in many urban areas, as well as the economic competitiveness and the overall sustainability of larger metropolitan regions. It is, therefore, important to focus our attention on the reasons behind increasing travel needs within the framework of a post carbon society. The choice of urban mobility policies can no longer be solely directed towards fighting the effects of current travel patterns. A broader understanding of the aspects influencing travel behaviour is crucial for the definition of effective low carbon mobility policies.

The 'predict and provide' paradigm of traditional transport planning is clearly inadequate for the management of current mobility needs. Within the new 'predict and prevent' paradigm, urban mobility management policies are facing new challenges. In this respect, the European Commission standpoint can be summarized in the following two main objectives: reduction of travel needs, and making remaining travel more sustainable. However, these simple and

straightforward objectives go well beyond the normal scope of transport planning. Several authors argue that the effective reduction of the environmental impact and carbon footprint of urban mobility requires the adoption of a truly holistic attitude. Indeed, the need to integrate land use and transport policies has been widely recognized as a more effective approach to meeting these new mobility requirements, than traditional transport planning policies. Nevertheless, these integrated policies have seldom been applied into practice. Furthermore, policies intended to address personal behaviours and choices, taking into consideration socioeconomic and demographic conditions are also being increasingly suggested, although, again, seldom implemented into practice.

## Objectives

The principal objective of this book is to present an assessment of the influence of alternative urban structures of metropolitan areas on corresponding mobility patterns. This research also recognizes the influence of socioeconomic and demographic characteristics. Although these characteristics are taken into consideration in our analysis, we will pay particular attention to the influence of urban structures on mobility, as the book title clearly suggests. In particular, two European metropolitan areas of similar sizes and different urban structures, Copenhagen and Oporto, will be compared. In the north, Greater Copenhagen portrays an essentially monocentric urban area with long established growth corridors, whereas Greater Oporto, in the south, still exhibits a marked polycentric structure, grounded in a distinct historic settlement pattern.

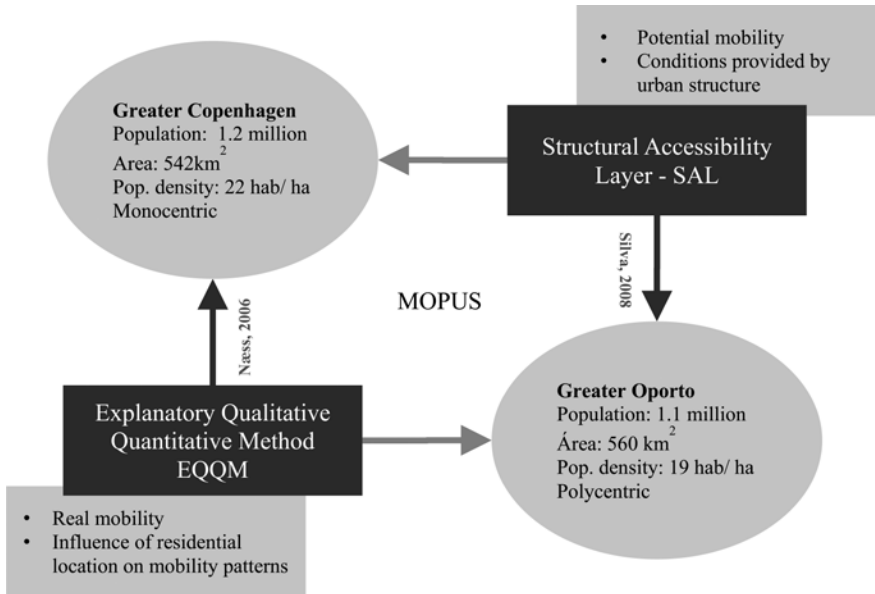

At a more detailed level, the reader will find the following associated or more operational objectives:

- to provide a deeper understanding of the relationship between urban structure and travel behaviour;
- to assess the accessibility potential of urban structures;
- to typify the relationships between travel behaviour and potential accessibility;
- to develop social profile and area based targeted policies to enhance low carbon mobility patterns in the case study areas of Greater Oporto and Greater Copenhagen;
- to recommend integrated land use and transport strategies tailored to the specific physical and functional characteristics of these two metropolitan areas; and
- to foster the combined application of structural and behavioural methodologies in mobility studies.

## Methodological Approach

This book presents the results of the MOPUS project (MOBility Patterns and Urban Structure), funded by the Fundação para a Ciência e a Tecnologia (FCT, the Portuguese Research funding agency) and was carried out between 2008 and 2010. The MOPUS project was based on two previous research projects concerned with complementary factors and motivations underlying urban passenger mobility patterns (Figure 1.1). One of these research projects, carried out in Portugal at the Research Centre for Territory, Transports and Environment (CITTA), was focused on the development of an innovative concept to be applied to urban and metropolitan areas, the so-called structural accessibility. This approach considers only structural factors, i.e., factors related to land use and transport systems, and was initially applied to Greater Oporto. The corresponding methodology, the *Structural Accessibility Layer (SAL)*, was designed to reveal the potential of land use and transport systems to provide the necessary conditions (although not necessarily sufficient in themselves) for more energy efficient mobility. In parallel, this innovative methodology is also able to provide a design-support tool for low carbon mobility policies.

The other research project, carried out at Aalborg University (Denmark), developed a complementary methodology; the *Explanatory Qualitative-*

**Figure 1.1 Research methodology: combined application of SAL and EQQM**

*Quantitative Method* (EQQM), and was initially applied to the Copenhagen Metropolitan Area. The aim of this methodology, focusing on behavioural aspects, is to identify the overall relationships as well as the more detailed mechanisms through which the location of residence is able to influence travel behaviour. In a number of important aspects the Copenhagen metropolitan study goes beyond the scope of previous investigations into the complex relationships between urban land use and travel patterns, including a comprehensive analysis of the socioeconomic and the attitudinal characteristics of travellers.

The possibility to combine these two complementary research methodologies is the distinctive and innovative contribution of this book. In addition to the first two experiments, referred to above, this combination will involve the application of the SAL to Greater Copenhagen and the application of the EQQM to Greater Oporto. In this way, the structural and behavioural aspects of mobility patterns will be analyzed and compared in both case studies, taking advantage of the previous work already carried out in both research centres. Despite the significant differences between the social and economic characteristics of the metropolitan areas of Oporto and Copenhagen (although fairly similar in area and population size) this book will provide clear evidence of the real importance of different metropolitan structures on mobility patterns.

Indeed, MOPUS was able to compare the mobility patterns of two important European metropolitan areas with contrasting internal structures – one predominantly monocentric (Greater Copenhagen) and the other historically polycentric (Greater Oporto). The exercise was also able to reveal the potentials of these methodologies to support the formulation of planning and transport policies for low carbon metropolitan areas, coming at a time of profound restructuring of public transport systems in many European countries.

## **Book Structure**

This book starts by presenting the research theme's background and motivation, as well as the principal and associated research objectives. This introductory chapter also includes a brief description of the general methodological approach adopted and the book's general outline.

The second chapter, on recent changes in urban areas, presents a brief overview of the cultural, social and demographic changes of contemporary societies and discusses their profound implications in people's travel behaviour and on the cities' mobility patterns. The chapter also addresses the relationships between the spatial and the functional structure of cities and related transport factors and motivations. The chapter concludes with a section on monocentric and polycentric models of urban development and associated implications for the emergence of distinctive urban travel patterns.

Chapter 3 presents a review of empirical evidences on the complex relationships between personal characteristics, urban structure and travel behaviour. The review

looks for motivations behind travel choices revealed by previous research, in particular research on the influence of personal characteristics and urban structure, namely land use and transport systems. With regard to the latter, particular attention was given to the influence of monocentric and polycentric urban structures on travel behaviour.

Chapter 4 presents the main case study areas – Greater Copenhagen and Greater Oporto – regarding geographical distribution of population and employment, the existing transport network and service level, as well as the main travel patterns identified.

The results of the literature review developed in Chapter 2 and Chapter 3 frames the research methods presented in Chapter 5 and Chapter 6, consisting of the combination of two previously developed, applied and tested methods: the *Structural Accessibility Layer* (SAL) and the *Explanatory Qualitative-Quantitative Method* (EQQM). Each method is presented in detail at the conceptual level, providing also insights for the practical applications on the two case study areas, briefly characterized in the previous chapter.

This is followed by two chapters (7 and 8) which present the results of the application of these two complementary methods in both case studies.

Chapter 7 summarizes the main results of the application of SAL to Greater Copenhagen and to Greater Oporto. This chapter discusses potential mobility choices made available (or disabled) by urban structure in each study area. The individual discussions are followed by the comparison of the potential mobility choices enabled by the two different urban structures in analysis. Results are compared to real modal choices in both areas in order to discuss connections between potential and real mobility patterns.

Chapter 8 summarizes the main results of the application of EQQM to both case studies. After a brief review of typical mobility patterns, this chapter presents the results of the analysis of the relationships between residential location and travel behaviour. Residential location is analyzed based on local density (combined population and job density), on the distance of residence to main and second order centres, to main railway stations and to main regional retail centres. Travel behaviour is analyzed based on travel distance (total and by mode) and mode share (based on values of mode travel distance). This chapter includes some remarks on the influence of residential location, such as distance to facilities and location of activities, on particular travel options. In addition, a discussion of the influence of residential location on travel across different population groups is also developed. In this discussion, especial attention is given to gender differences.

The book ends with Chapter 9 which summarizes the main lessons learned throughout the entire MOPUS research project, and the conclusions and recommendations, which are twofold: of a general nature for spatial and transport planning theory and practice, and of a specific nature, relevant to each metropolitan area under analysis.
